1 Introduction

1.1 Definitions

- **Streaming:** The process of transmitting and/or receiving media content over the internet in real time and in a continuous manner.
- **Open Source Program:** Software and its source code for which it is publicly available to view, use, distribute, and modify without restriction.
- **Closed Source Program:** Software whose source code is either partially or fully restricted from public access, which is usually developed and maintained by a private company or organization.

1.2 Context

Ever since the turn of the millenium, the internet has had a significant impact on global communication technologies. By the year 2000, 51% of global telecommunications networks were transmitted via the internet, a figure that rose to 97% by 2007 (Hilbert & López, 2011). This reliance on the internet has been steadily increasing over time, culminating in 2020 when quarantine and lockdown measures due to the pandemic made the internet an essential part of daily life for most people worldwide. This drastic change in people's lives led to an all-time high demand for applications that connect different individuals through digital means, such as Meta's Metaverse, the increased demand for virtual meeting software (Zoom, Google Meet, Microsoft Teams), and mass communication services like Discord and Slack.

It is in this context that the need to adapt these daily activities to a new digital environment arises; in this case, broadcasting and sharing multimedia content via streaming from one device (host) for others to view on their devices in real time, regardless of their geographical location. Media streaming became popular through formal or academic means such as Zoom and Microsoft Teams, while the more casual media streaming needs were dominated by platforms like Twitch and Discord (the latter, although primarily used as a social messaging platform, also offers VoIP and video streaming services, which is the relevant service for this paper). The rapid expansion of video traffic on the internet, coupled with the staggering amount of users of these services, has created a strong need to develop robust protocols that work

quickly and efficiently under any type of connectivity conditions, as well as infrastructures that are sufficiently robust and scalable to meet the demand for these transmissions.

This has led to an interest by developers to restrict in certain ways some functionalities and features offered by these streaming services in a way that is actually profitable. Paywalls and subscription models are some of the most common ways companies and services implement a restriction that solves multiple problems at the same time: first of all, it limits the number of users that can use the service at any given moment, which reduces maintenance costs and bandwidth usage; second, it produces a source of income for the service provider, which can be used to improve the service and infrastructure; and third, it helps create a sense of exclusivity to the paying user. Some services that include these kinds of subscriptions are Discord, Google Meet, and Zoom. In the case of Discord, the service offers a subscription called Nitro that, besides other benefits, allows the user to upgrade the stream quality from the free tier cap of 720p x 30fps to a maximum of 4k x 60fps, with a monthly cost of $9.99 USD (as of November 2026). With Google Meet, the free tier besides allowing a call for only up to 60 minutes, hard limits the stream quality to 720p x 30fps, while any of Google's subscriptions allows for a maximum of 1080p x 30fps. Zoom, on the other hand, does not really restrict the stream quality, allowing content to be shared in the native resolution at 30fps for no extra cost, but it does recommend downscaling to 1080p to save on bandwith. It also limits the free tier to 40 minutes per call, restricting the user not by the quality of the stream, but by the time they can use it.

Given the context of these service models with their constraints, it becomes apparent that users, even though there are multiple options for meeting their streaming needs, are still limited by the restrictions imposed by these companies. Open source projects are alternatives to these services, but even though they can be more beneficial than closed-source by improving security, allowing way more flexibility, and fostering community involvement by having collaborative development [1], there are many chases in which these alternativesare not as widespread and used as the commercial ones. This lower popularity directly reduces the appeal to the common user to move onto these alternatives. Regardless, there exist a myriad of open source projects that act as cornerstones of the modern internet and computing as a whole. Some of the main examples typically include the Linux kernel, one of, if not the most, important operating system kernels worldwide, the Apache

web server, MySQL, and PHP, all four being the main components of the LAMP stack. And even outside of the scope of giant corporations running open source, even more projects exist that are maintained by small teams or even individuals. There are many cases of these projects existing without an explicit commercial or financial interest, but rather as a means to solve a specific need, desire or problem someone encountered. Hausberg et al. [2] states how motivations behind OSS (Open Source Software) contributions stem from the individual's desire to contribute towards innovation that becomes a common good. It can be seen as the rational choice to provide a contribution for free, as the result afterwards becomes a private, ongoing benefit. It is through this reasoning that one may explain the reasoning behind these projects taking off and staying relevant, even in the face of competition from commercial alternatives.

1.3 Motivation

Due to the large amount of corporate-maintained software on many aspects of every day technological life, there has always been an interest on open source software development and maintenance. The democratization of software presents a unique opportunity for developers to create tailor-made solutions to their own problems or needs, benefitting from having a community of developers and users that can contribute to the project either by providing feedback, reporting bugs, contributing code, or by financially backing the project. Besides from the characteristic of it being a private or open source project, developing a streaming service application involves a considerable amount of technical knowledge and integration in order to provide a robust and efficient alternative for the user. Since it involves concepts of networking, video and audio encoding, synchronization, and UI/UX design, working on a streaming service application is a great way to learn by creating something tangible and useful, while also allowing a community of users to both support and benefit from it. Another motivation stems from more personal reasons, as the distaste of corporate software coupled with the desire to watch movies with people who are geographically far away made way for this project idea to be born.

1.4 Objectives

1.4.1 Main Objective

1.4.2 Secondary Objectives

2 Methodology

2.1 State of the Art
